ABSTRACT

Introduction and objectives: Today it has become increasingly common to perform procedures without withdrawing oral anticoagulation. However, the need to withdraw oral anticoagulants prior to cardiac catheterization in patients chronically anticoagulated (OACs) remains controversial. We evaluated the efficacy and safety of performing transradial catheterization in outpatients without withdrawing direct-action oral anticoagulants (DOACs).

Methods: Prospective and observational study where 270 patients who underwent elective transradial cardiac catheterization were included from January 2013 through November 2017, divided into 3 groups of 90 patients based on their anticoagulant intake: group A (without OAC), with group B (with vitamin K antagonist), and group C (with DOACs), and matched according to the date of completion. In no case was the OAC discontinued before the procedure. We evaluated the complications of radial access within the first 24 h and 1 month after the procedure.

Results: The group of patients on DOACs had a higher proportion of men compared to the vitamin K antagonist group (71.1% vs 47.8%; \( P = .01 \)) and patients were younger in the group without OAC (63.45 ± 11.47 vs 70.22 ± 9.35; \( P = .03 \)). Group B had a lower percentage of diabetic patients (22.2% vs 36.67% in group C, \( P = .03 \)). In group A, patients were more prone to having a history of ischemic heart disease compared to the groups of anticoagulated patients (27.84% vs 14.44% in group C, \( P = .028 \)) in addition to a more frequent intake of antiplatelet drugs. Radial access was the access of choice in most patients (98.2%). There were no significant differences when it comes to vascular access complications among the groups being the rate of hematoma and/or bleeding at discharge equal to 1.1% in the DOACs group and the arterial occlusion rates both at discharge and at 1 month between 0% and 2.2%.

Conclusions: In our experience performing transradial diagnostic cardiac catheterizations without discontinuation of DOACs is safe, with low rates of thrombotic and hemorrhagic complications, without any differences with vitamin K antagonist and no OAC.

Seguridad del cateterismo diagnóstico ambulatorio en pacientes en tratamiento con anticoagulantes orales de acción directa

RESUMEN

Introducción y objetivos: Actualmente es cada vez más habitual realizar procedimientos sin retirar la anticoagulación oral (ACO), pero la necesidad o no de suspender la ACO antes del cateterismo cardíaco sigue siendo una cuestión controvertida. Se evalúan la eficacia y la seguridad de la realización de un cateterismo transradial en pacientes ambulatorios sin retirar los anticoagulantes orales de acción directa (ACOD).

Métodos: Estudio observational, prospectivo, que incluye 270 pacientes sometidos a cateterismo transradial electivo desde enero de 2013 hasta noviembre de 2017, divididos en 3 grupos de 90 pacientes: grupo A (sin ACO), grupo B (con antagonista de la vitamina K), grupo C (ACOD), emparejados según la fecha de realización del cateterismo. No se suspendió la ACO antes del procedimiento. Se evaluaron las complicaciones del acceso radial en las primeras 24 h y un mes después del cateterismo.

Resultados: Había más varones tratados con ACOD que con un antagonista de la vitamina K (71,1 frente a 47,8%; \( p = 0,01 \)) y los pacientes eran más jóvenes en el grupo sin ACO (63,45 ± 11,47 frente a 70,22 ± 9,35 años; \( p = 0,03 \)). En el grupo B hubo menos
INTRODUCCIÓN

El número de pacientes que reciben anticoagulación oral crónica (COAC) es enorme, y se espera un aumento en el futuro debido a la edad creciente de la población y la incidencia aumentada de condiciones que requieren COAC.

La frecuencia de COAC entre pacientes con enfermedad coronaria que reciben interrupción crónica de intervenciones coronarias es del 6% y el 8%. La mayoría de los casos se deben a la presencia concurrente de fibrilación atrial con moderada-alta probabilidad embólica.

En el otro lado, entre el 20% y el 30% de los pacientes con fibrilación atrial y una indicación de COAC presentan enfermedad coronaria. La práctica rutinaria con estos pacientes es muy variable, pero tradicionalmente los pacientes con COAC han disminuido el uso del medicamento y se ha movido a tratamiento de bridge (BT) con heparina de bajo peso molecular (LPMB). En nuestra serie, el 21.3% de los pacientes recibieron heparina en una dosis única. En nuestro estudio, el 25.2% de los pacientes recibieron heparina durante el procedimiento.

Hay, por lo tanto, un número significativo de pacientes que reciben medicación anticoagulante (ACO) con antagonistas de la vitamina K (VKA) o uno de los más recientes anticoagulantes orales directos (DOACs, Edoxaban, Rivaroxaban, Dabigatran). La prevalencia de fibrilación atrial en la población es del 1% al 2%, y hasta el 1,2% de los anticoagulados en Europa se verá afectado por una angiografía en el futuro.

El diagnóstico y tratamiento de cateterismo diagnóstico radial sin interrupción de los COAC se ha evaluado en este tipo de pacientes en el pasado. En nuestro grupo, el protocolo de diagnóstico se ha mantenido con éxito en pacientes con COAC, con tasas bajas de complicaciones trombóticas y hemorrágicas, sin diferencias respecto a los pacientes en tratamiento con un antagonista de la vitamina K o sin ACO.

BT: bridging therapy. COAC: chronic oral anticoagulation. DOAC: direct-acting oral anticoagulants. VKA: vitamin K antagonists
They underwent elective transradial cardiac catheterization with same-day discharge, after removing the compression bandage and achieving hemostasis. All cases were conducted through one hydrophilic 5-Fr sheath. Hospitalized patients who underwent diagnostic catheterization were excluded as well those in whom an angioplasty procedure was anticipated.

All procedures were conducted in a single interventional cardiology unit with huge experience using transradial access [over 90% of all cases annually] and with an active program of same-day discharge outpatient cardiac catheterizations.6,8

Procedural characteristics
All patients are welcome at a room near the interventionist laboratory and are evaluated by a nurse specialized in their monitoring and follow-up. This nurse is in charge of informing the patients, collecting the patient’s background, verifying the doses and time of the last COAC intake, and estimating the INR in patients on acenocoumarol. After informing the patient and collecting the informed consent, the best vascular access is selected, assessing the quality of the pulse and performing the Barbeau test.

Once the procedure is completed, the radial compression is performed using the patent hemostasis technique for, at least, 2 h. Radial patency and possible complications are assessed in this room prior to the patient’s discharge. The complications and outcomes of the vascular approach we assessed were: acute bleeding (with need to extend the length of compression), hematoma 5-10 cm at discharge, radial patency at discharge, bleeding and/or hematoma at 24 h, radial patency at 1 month and the presence of other unusual complications (pseudo-aneurysms, fistulas, arterial perforations, or compartment syndrome). For hematoma classification, the EASY criteria were used.10 The compression of the vascular access was made with swab and elastic bands for 2 h using the patent hemostasis technique11 where distal permeability is verified through plethysmography. Additionally, a 30 min extra-compression was performed if the puncture bled when the bandage was removed. In order to assess radial patency after the removal of compression, the test described by Barbeau et al. was used.12 Artery occlusion was defined by type D response [no recovery of the curve of pulse in 2 min]. All patients were contacted via telephone over the following 24 h after the procedure to determine delayed local complications, and they were all followed during 1 month to determine the access occlusion.

Statistical analysis
Data are expressed as absolute rate and percentage for qualitative variables. Quantitative variables are expressed as mean ± standard deviation) or median 25–75 interquartile range depending on variable distribution. Group comparisons were analyzed using the Student t test or its non-parametric equivalent; the Mann-Whitney U-test for continuous variables, and chi-square test or Fisher’s exact test were used for the categorical variables. Statistical significance was defined as P values < .05. The statistical analysis was conducted using the statistical package SPSS 19.0 [SPSS, Inc.; Chicago, Illinois, United States].

RESULTS
The patients included in the study were assigned to three groups of 90 individuals each and matched by date of procedure: one group without oral anticoagulation (group A), another group with anti-vitamin K treatment (group B) and another with direct-acting anticoagulants (group C).

The indication of oral anticoagulation in group B mostly corresponds to patients with atrial fibrillation (74.4%), 26.7% of patients had valvular disease and 5.6% of them were carriers of mechanical prostheses; the remaining patients received anticoagulation due to a past medical history of embolism [5.6%], dilated cardiomyopathy [1.1%] and other causes.

The baseline characteristics of our patients are shown on Table 1. The group treated with DOACs had a higher proportion of men than the VKA group ([71.1% vs 47.8%; P = .01] and patients were younger in the group without oral anticoagulation (63.4 ± 11.5 vs 70.2 ± 9.3; P = .03). Group B had a lower percentage of diabetic patients (22.2% vs 36.67% in group C, P = .03). Group A patients had a past medical history of ischemic heart disease more frequently than the groups of anticoagulated patients (27.84% vs 14.44% in group C, P = .028) and therefore, they had undergone previous catheterization using the same access in higher percentages [20% group A vs 5.5% in group C, P = .04].

When it comes to the concomitant treatment with antiplatelet agents, patients without COAC took acetylsalicylic acid more frequently (72.2% vs 12.2%; P < .0005) compared to the DOACs group, as well as clopidogrel [23.3% vs 4.4%; P < .0005]. Acetylsalicylic acid was also more widely used in the DOACs group compared to the VKA group [12.2% vs 3.3%; P = .048]. All this is probably related to a greater suspicion of ischemic heart disease in these patients. There were only 2 patients treated with prasugrel and one with ticagrelor in the group without COAC.

There were no other significant differences on the remaining baseline characteristics [high blood pressure, dyslipidemia, body mass index, smoking...].

Radial access was the access of choice in most patients [98.2%], and ulnar access in the remaining patients. Regarding complications (Table 2) of vascular access, during the procedure and during the 24 h and 1 month follow-up, there were no significant differences, showing a rate of hematoma and/or bleeding at discharge of 1.1% in the DOACs group and arterial occlusion rates both at discharge and at 1 month between 0-2 an 2% in this group. Only one patient needed hospitalization due to prolonged radial bleeding.

DISCUSSION
The performance of diagnostic cardiac catheterizations without withdrawing COAC is recommended in the guidelines17 and our standard routine here at our unit of hemodynamics and interventional cardiology is using mostly radial access (95%) excellent safety results.18

The information comes basically from studies conducted in patients under treatment with VKA. Two meta-analyses that addressed this issue14,15 conclude that performing catheterizations without withdrawing COAC is safe and effective. The study published by the Finnish group led by Karjalainen16 also assessed the safety profile comparing it to a group of patients on COAC and heparin BT. They found a rate of bleeding significantly higher in the latter group (1.7% vs 8.3%), being higher in the COAC-BT withdrawal group compared to the withdrawal group of COAC without BT (2.5% vs 8.3%). Also, if the procedure is done through radial access, the results in terms of bleeding are even better.17

a No OAC (group A) vs DOAC (group C).
b VKA (group B) vs DOAC (group C).
c DOAC (group C) vs groups A + B.

However, when talking about patients on DOAC treatment, the evidence is scarce and there is no consensus. The current guidelines on revascularization do not include the recommendation of keeping oral anticoagulation during the procedure, but in recent expert consensus statements published by different international societies, there is controversy on this issue. Thus, due to the lack of existing evidence, the European document of antithrombotic consensus recommends to not stop anticoagulation in the case of VKA, but pre-withdraw DOACs between 12 and 24 h (24-48 h in the case of dabigatran) in patients who will undergo the intervention. On the other hand, in the document on preoperative and perioperative antithrombotic management they recommend to not withdraw antithrombotic treatment with DOACs in low-risk hemorrhagic procedures such as transradial diagnostic catheterizations because of its lower rate of vascular complications, especially when it comes to bleeding.

Despite all this, the standard practice with these patients is variable, but as a rule of thumb most hemodynamic laboratories worldwide withdraw COAC and move on to BT with low molecular weight heparin a few days before and after the procedure. However, there are more hemorrhagic events with this strategy when performing interventional procedures as well as more morbidity and mortality of these patients due to bleeding or prothrombotic situations that are created when withdrawing and resetting anticoagulant therapy.

With the increasingly use of DOACs, new problems arise in our routine clinical practice when these drugs need to be withdrawn before performing procedures and it is common to see that in these patients BT is prescribed the same way as it is prescribed in patients undergoing VKA treatment from many medical and surgical specialties, although its use in recent consensus documents is not recommended.

When it comes to cost-effectiveness, the BT strategy is a tremendous cost overrun due to several aspects: the higher incidence of hemorrhagic complications in patients who will need medical attention, the high cost of low molecular weight heparin, longer hospital stays, and the need to analyze the levels of anticoagulation...
in patients under treatment with VKA. In other areas of interven-
tional cardiology, progress has been made on this regard and cost-
effectiveness studies have been conducted on this question, such
as the study conducted by Coyle et al. that showed that the
non-prescription of BT saved US$ 1800 per patient following some
the aforementioned aspects. Also, If we compare DOACs and VKA
drugs, a recent study conducted by Shah et al. in patients with
permanent atrial fibrillation showed that all DOACs proved supe-
rior in a cost-effectiveness model that included quality-of-life ad-
justed survival, with dabigatran being the most cost-effective drug
in patients with the highest thrombo-embolic risk of all.

The main conclusion that we can draw from this study is that it
is safe to perform diagnostic cardiac catheterizations through tran-
sradial access in patients on chronic anticoagulation with DOACs.
These patients do not have more frequent vascular or bleeding
complications compared to those under standard therapy.

When it comes to bleeding complications, there was a low inci-
dence rate in all groups without any significant differences. An-
other thing to take into consideration in the case of DOACs is the
possibility of anticoagulation reversal with the specific antidote
(currently only available for dabigatran and about to be on the
market for factor Xa inhibitors) in case of serious complications
which gives us a greater safety profile when performing invasive
procedures with these drugs.

In our population, the incidence of radial occlusion was exception-
ally low in all groups. Early (< 24 h) and late occlusions (1 month)
occurred in 2.2% and 0% of the patients from the DOAC group;
in 3.3% and 2.9% of the patients from theacenocoumarol group
compared to 3.3%; and in 3% of the patients from the heparin
group without any statistically significant differences. Previous
studies have reported extremely low rate of occlusions, even low-
er than 1%.23

We have not found in the medical literature any series similar to
ours, although there are numerous series in which coronary angi-
ographies are performed without withdrawing COAC with VKA,
with results that are consistent with ours.8,25,26

There have been trials with DOACs in percutaneous coronary
interventions that have not found any differences in the clinical
adverse events (bleeding, embolism, ischemia) in patients in whom
the percutaneous coronary intervention was conducted under dif-
f erent anticoagulation strategies.27,28

Study limitations and future directions
The low incidence of complications and the small size of the sam-
ple did not allow us to conclude any significant statistical differ-
ences among the groups. It would be necessary that the size of the
sample was larger, which is difficult in a single center. Maybe a
multicenter registry could shed some more light on this issue.

Nowadays, the number of patients under acenocoumarol or war-
farin treatment is rapidly dropping due to the exponential use of
new anticoagulant drugs as dabigatran, apixaban, rivaroxaban,
and edoxaban. In sum, new and larger studies on direct-acting
oral anticoagulants should be conducted on this regard.

CONCLUSIONS
The performance of outpatient diagnostic catheterizations using
the radial access without withdrawing the DOAC treatment seems
to be safe and does not bring a greater deal of complications com-
pared to patients under treatment with acenocoumarol or without
anticoagulant treatment. It would be advisable to conduct random-
ized studies to be able to confirm these data.

CONFLICTS OF INTEREST
We declare no conflicts of interest whatsoever.

WHAT IS KNOWN ABOUT THE TOPIC?
- Currently there is no consensus on the management
of oral anticoagulation in patients taking direct-act-
ing oral anticoagulants undergoing procedures such
as diagnostic coronary catheterizations. In some
centers anticoagulation is kept, resembling clinical
practice in the management of antivitamin K, in
others it is withdrawn even performing bridging
therapy with heparin in some cases. Both the clin-
ical practice guidelines and current consensus docu-
ments do not agree on what our approach should be
with these patients since evidence is scarce.
WHAT DOES THIS STUDY ADD?
- We believe that our study is of great interest for routine clinical practice, due to the growing use of direct-acting oral anticoagulants in all physicians’ daily practice, including cardiologists and interventional cardiology. The use of these drugs has increased exponentially so it is not rare to find patients who are going to undergo a coronary angiogram who are taking DOACs. That is why we wanted to share the experience of our hemodynamic laboratory with this type of patients and show the efficacy and safety profiles of these drugs in this field.
